Furanone Derivatives as Inhibitors of Cathepsin S

Field of the invention.

Cathepsin S is a highly active cysteine protease belonging to the papain superfamily. Its primary structure is 57%, 41% and 45% homologous with that of the human cathepsin L and H and plant cysteine proteases papain respectively, although only 31% homologous with Cathepsin B.

It is found mainly in lymph nodes, spleen, and macrophages and this limited occurrence suggests the potential involvement of this enzyme in the pathogenesis of degenerative disease.

Moreover, it has been found that destruction of Ii by proteolysis is required for MHC class II molecules to bind antigenic peptides, and for transport of the resulting complex to the cell surface. Furthermore, it has been found that Cathepsin S is essential in B cells for effective Ii proteolysis necessary to render class II molecules competent for binding peptides. Therefore, the inhibition of this enzyme may be useful in modulating class II-restricting immune response (WO 97/40066).

Selective inhibition of a single protease in a complex mixture of proteolytic enzymes and more especially over other members of the same enzyme class or family is imperative as incorrect regulation of proteolytic activity can lead to unwanted pathological conditions such as hypertension, blood clotting or worse. This has led to the search for inhibitors that selectively inhibit only one member of a proteolytic family, a problem that is very relevant to the Cathepsin family, which have a high degree of homology.

The invention relates to novel protease inhibitors, particularly inhibitors of the cysteine proteases of the papain superfamily and more particularly to Cathepsin S. The inhibitors of the invention are selective over other members of the family and in particular show selectivity over other members of the Cathepsin family such as L and K.

Description of the related art.

In WO 97/40066, the use of inhibitors against Cathepsin S is described. The inhibition of this enzyme is suggested to prevent or treat disease caused by protease activity.

WO 98/50533 describes the use of compounds according to the formula (I).

It is suggested the compounds of this formula, known as the tetrahydrofuran-3-ones, are useful as inhibitors to proteases, in particular the papain superfamily; specifically those of the Cathepsin family; and particularly Cathepsin K.

- 7 -

and optionally other therapeutic ingredients. The carrier(s) must be acceptable in the sense of being compatible with the other ingredients of the formulation and not deleterious to the recipient.

The formulations include those suitable for rectal, nasal, topical (including buccal and sublingual), vaginal or parenteral (including subcutaneous, intramuscular, intravenous and intradermal) administration, but preferably the formulation is an orally administered formulation. The formulations may conveniently be presented in unit dosage form, e.g. tablets and sustained release capsules, and may be prepared by any methods well known in the art of pharmacy.

Such methods include the step of bringing into association the above defined active agent with the carrier. In general, the formulations are prepared by uniformly and intimately bringing into association the active agent with liquid carriers or finely divided solid carriers or both, and then if necessary shaping the product. The invention extends to methods for preparing a pharmaceutical composition comprising bringing a compound of Formula I or its pharmaceutically acceptable salt in conjunction or association with a pharmaceutically acceptable carrier or vehicle. If the manufacture of pharmaceutical formulations involves intimate mixing of pharmaceutical excipients and the active ingredient in salt form, then it is often preferred to use excipients which are non-basic in nature, i.e. either acidic or neutral.

- Formulations for oral administration in the present invention may be presented as discrete units such as capsules, cachets or tablets each containing a predetermined amount of the active agent; as a powder or granules; as a solution or a suspension of the active agent in an aqueous liquid or a non-aqueous liquid; or as an oil-in-water liquid emulsion or a water in oil liquid emulsion and as a bolus etc.

Flavouring agents such as peppermint, oil of wintergreen, cherry flavouring or the like can also be used. It may be desirable to add a colouring agent to make the dosage form readily identifiable. Tablets may also be coated by methods well known in the art.

A tablet may be made by compression or moulding, optionally with one or more accessory ingredients. Compressed tablets may be prepared by compressing in a suitable machine the active agent in a free flowing form such as a powder or granules, optionally mixed with a binder, lubricant, inert diluent, preservative, surface-active or dispersing agent. Moulded tablets may be made by moulding in a suitable machine a mixture of the powdered compound moistened with an inert liquid diluent. The tablets may be optionally be coated or scored and may be formulated so as to provide slow or controlled release of the active agent.

Other formulations suitable for oral administration include lozenges comprising the active agent in a flavoured base, usually sucrose and acacia or tragacanth; pastilles comprising the active agent in an inert base such as gelatin and glycerin, or sucrose and acacia; and mouthwashes comprising the active agent in a suitable liquid carrier.

Compounds are synthesised by a combination of chemistries, performed either in solution or on the solid phase. The general scheme for preparation of the furanone ring system is given in scheme 1, commencing from either a commercially available chiral aminoacid derivative or a stereoselectively prepared aminoacid, for instance from Scheme 2.

The stereoselective synthesis detailed in Scheme 2 was adapted from Blaskovich, M.A., Evinder, G., Rose, N. G. W., Wilkinson, S., Luo, Y. and Lajoie, G. A. *J. Org. Chem*, 63, 3631-3646, 1998. The addition of Grignard reagent to compound (10) yielding the (R) isomer of compound (11) is applicable to a huge range of alternative Grignard reagents. This allows ready access to analogues of compound (15) by standard Grignard chemistry to produce R5 analogues embraced by formula (II). The R5 substituent confers many beneficial qualities to molecules of general formula (II) including improvements in potency, selectivity and offers the potential to append inhibitor molecules with a basic functionality to improve solubility and pharmacokinetic properties. Additionally, molecules of formula (II) where R5 is alkyl and not simply hydrogen show good chiral stability at the furanone alpha carbon (ring position 4).

Note particularly the presence of the substituent R5 in formula (II) in comparison with the absence of any substituent in the same position in formula (I) according to WO 98/50533.

An alternative route towards chiral β -alkyl serine aminoacids is detailed in scheme 3, commencing from D-mannitol. The addition of organocuprate reagents to the advanced oxirane intermediate (44) is applicable to a wide selection of reagents, giving ready access to analogues of compound (15) ie analogues of R5 in formula (II).

To access molecules containing potential binding elements in R6 formula (II), a number of synthetic chemistry routes are available. One example extends the basic concepts developed for the preparation of the furanone ring system depicted in

schemes 1 and 8 (scheme 4). Intermediate (51), which can be prepared with alternative ring stereochemistries from alternative threonine isomers, provides access to the functionalities defined in R6 formula (II).

An alternative route to access molecules containing potential binding elements in R6 from formula (II), is based upon transformation of a chiral sugar starting material (scheme 5). Intermediate (59), which can be prepared with alternative ring stereochemistries from alternative starting sugar isomers using conventional saccharide chemistry, provides access to many functionalities in R6 formula (II).

Many active inhibitors contain commercially available amino acid residues such as L-leucine, L-norleucine etc (see table 1). Alternatively, active inhibitors contain new and novel hydrophobic amino acids, which are prepared following the chemistry detailed in scheme 6. The synthesis detailed in Scheme 6 was adapted from Dexter, C. S. and Jackson, R. F. W. *Chem. Commun.* 1, 75-76, 1998, and allows ready access to analogues embraced by R3 in formula (II). The side chains of some of the novel, multiply branched alpha-amino acid building blocks exemplified herein can be thought of as hybrids of the properties of combinations of other amino acid side chains, such as those of norleucine and t-butylalanine and are thus referred to as "hybrids" in the tables.

The furanone building blocks (synthesis exemplified in Scheme 1) are utilised in a solid phase synthesis of inhibitor molecules (typically 5-25mg product) detailed in Scheme 7. Alternatively, for larger scale syntheses, full preparation of inhibitors by solution phase chemistry may be performed as detailed in Scheme 8.

Compounds were previously named (for instance in the priority document GB 9911417.5) using amino acid nomenclature i.e. a sidechain of 2,2-dimethylpropyl was termed the aminoacid *tert*-butylalanine. The current specification contains novel aminoacids for which common names are not available. Therefore, all previously

exemplified and new compounds are re-named following IUPAC guidelines. For example, the compound below was previously named :-

Dihydro-(4-(S)-Amino-N-[(3-furanoyl)-*tert*-butyl-L-alanine])-5-(S)-methyl)-3(2H)-furanone

Under the new naming regime, the compound will be termed as:-

Furan-3-carboxylic acid [3,3-dimethyl-1S-(2S-methyl-4-oxo-tetrahydrofuran-3S-ylcarbamoyl)butyl]amide.

Unless otherwise specified, where a chiral centre is present in a molecule but not assigned, both R and S isomers are intended.

Furan-3-carboxylic acid [3,3-dimethyl-1S-(2-ethyl-4-oxo-tetrahydrofuran-3-ylcarbamoyl)butyl]amide,

Example molecules prepared using the general chemistries outlined above and by the methods detailed in the experimental are shown in Tables 1 and 2. Judicial combination of R1, R3 and R5 substituents in general formula (II) yields potent and selective inhibitors of cathepsin S e.g. Furan-3-carboxylic acid [3,3,4-trimethyl-1S-(2S-ethyl-4-oxo-tetrahydrofuran-3-ylcarbamoyl)pentyl]amide:

Ki mammalian cath S (15nM), murine cath S (149nM) rat cath S (271nM), cathepsin L (> 100µM), cathepsin K (5.5µM). Molecules may be chosen which show a range of activities for mammalian, murine and rat cathepsin S (see Table 2) which may exemplify many facets of an inhibitor development programme e.g. activities in murine or mammalian cell-based assays, dosing of species for disease-related animal models etc.

Molecules of general formula (II) have the potential for good oral bioavailability e.g.

Solution Phase Chemistry

Example 1. Furan-3-carboxylic acid [3,3-dimethyl-1S-(2S-methyl-4-oxo-tetrahydrofuran-3S-ylcarbamoyl)butyl]amide (4)

Following general chemistry scheme 8

(a) General method for the synthesis of N-Boc protected diazoketones, exemplified by (2S, 3S)-N-Boc-O-t-butyl-L-threonyldiazomethane (1)

(2S, 3S)- N-Boc-O-t-butyl-L-threonine (1.2g, 4.2mmol) was dissolved in dry DCM (20mL) and N-methylmorpholine (1mL, 2.2eq) added. The reaction mixture was cooled to -15°C and stirred under an atmosphere of argon. Isobutyl chloroformate (0.56mL, 4.3mmol) was added and the mixture stirred for 10mins at -15°C . A solution of diazomethane in diethyl ether (45mL, approx 40mmol) was added and the reaction allowed to warm to room temperature over 1hr, then acetic acid was added dropwise until effervescence had ceased. The reaction mixture was diluted with DCM (100mL) and washed successively with saturated aqueous sodium bicarbonate (2 x 75mL), water (75mL) and brine (75mL) and dried over sodium sulphate. The solvent was removed *in vacuo* to give crude (2S, 3S)-N-Boc-O-t-butyl-L-threonyldiazomethane (1.2g, ~100%) as a pale yellow oil. The above synthesis was repeated 9 times and the total crude product pooled (12g) and used without purification for the next stage.

(b) General method for the synthesis of Boc-3(2H)-furanones, exemplified by dihydro-(4S-amino-[N-Boc])-5S-methyl-3(2H)-furanone (2)

A solution of lithium chloride (13.6g, 320mmol) in 80% aqueous acetic acid (400mL) was cooled to 5°C and added to crude (2S, 3S)-N-Boc-O-t-butyl-L-threonyldiazomethane (1) (9.6g) with stirring. The oil dissolved over 10mins and stirring continued for a further 1hr slowly warming to room temperature, with evolution of gas. The solvents were removed *in vacuo* and the residue taken into EtOAc (250mL) and washed successively with water (250mL), saturated aqueous sodium bicarbonate (2 x 100mL) and brine (75mL), then dried over sodium sulphate. The solvent was removed *in vacuo* and the crude product purified by flash chromatography over silica gel (150g) eluting with EtOAc / heptane (1:2, v/v). Two fractions were pooled and the quicker eluting fraction reduced *in vacuo* to approx 50mL heptane and left to crystallise to give dihydro-(4S-amino-[N-Boc])-5S-methyl-3(2H)-furanone (2) as a white solid, yield 4.05g, 18.8mmol, 58%. Electrospray-MS m/z 216 (MH^+), 160 ($MH^+ - 56$), elemental analysis $C_{10}H_{17}O_4N$ (req) %C 55.80, %H 7.96, %N 6.51, (fnd) %C 55.82, %H 7.86, %N 6.44.

(c) General method for N-terminal extension, exemplified by dihydro-(4S-amino-[N-Boc-L-*tert*-butylalanyl])-5S-methyl-3(2H)-furanone (3)

Furan-3-carboxypentafluorophenyl ester (0.88g, 1.05eq) and 1-hydroxybenzotriazole hydrate (0.48g, 1.05eq) were dissolved in DMF (15mL) and after 5mins added to the above salt. The clear solution was then treated with N-methylmorpholine (0.33g, 0.36mL, 1.1eq) and left at room temperature for 2hrs, producing a dark solution. The solvents were removed *in vacuo* and the crude product purified by flash chromatography over silica gel (50g) eluting with EtOAc / heptane (3:2, v/v). Fractions were pooled and reduced *in vacuo* to give Furan-3-carboxylic acid [3,3-dimethyl-1S-(2S-methyl-4-oxo-tetrahydrofuran-3S-ylcarbamoyl)butyl]amide (4) as a pale tan solid, yield 0.45g, 1.35mmol, 45%. Exemplified by dihydro-(4S-amino-[N-Fmoc])-5S-ethyl-3(2H)-furanone (**18**), following the general chemistry detailed in scheme 1.

(a) Preparation of Fmoc-(2S,3S)- β -ethylserine (**16**)

- 42 -

(2S,3S)- β -hydroxynorvaline (15) (277mg, 2.07mmol) and sodium carbonate (2.1eq, 460mg) were dissolved with stirring and ice-cooling in water (25mL) and THF (10mL). 9-fluorenylmethyl chloroformate (1.05eq, 560mg) in THF (15mL) was added over 45mins and the mixture stirred for a further 1hr at room temperature. Chloroform (100mL) and water (50mL) were added and the mixture acidified to pH2 with 0.1N HCl. The organic layer was collected and the aqueous washed with a further 2 x 100mL chloroform. The combined organics were backwashed with brine (1 x 300mL) and dried over magnesium sulphate. The chloroform was reduced *in vacuo* to yield a fine white solid. The solid was dissolved in *tert*-butyl methylether (25mL) with heating and heptane (75mL) added to give a cloudy solution. The mixture was cooled to -20°C and each 30mins further heptane (75mL) added for 4 cycles. The precipitate was filtered off and dried *in vacuo* to a fine white solid (16) 590mg, 80.6 %; TLC (CHCl_3 ; MeOH 3:1) $R_f = 0.40$, electrospray-MS m/z 356.2 (MH^+).

Dihydro-3(2H)-furanone (18, 24-28), (1.0eq) was dissolved in a mixture of ethanol / water (7:1 v/v, 10mL per mmole compound) containing sodium acetate trihydrate (1.5eq). 4-[[[(hydrazinocarbonyl)amino]methyl]cyclohexanecarboxylic acid trifluoroacetate (mw 329.3, 1.0eq) (see Murphy, A. M., *et al*, *J. Am. Chem. Soc.*, 114, 3156-3157, 1992) was added and the mixture heated under reflux for 2hrs. The mixture was then cooled, poured into dichloromethane (100mL per mmole compound) and water (100mL) added. The organic layer was separated, backwashed with saturated brine (100mL). The organic layer was dried (Na_2SO_4), filtered and evaporated *in vacuo* to yield a white solid. Yield 85 – 105% crude weight.

TFA (2mL) and water (40mL) were added to compound (54) (1.18g, 4.14mmol) and the solution was stirred at room temperature overnight. The solvent was then evaporated *in vacuo* to produce a colourless oil. The crude oil was then dissolved in water (34mL) and stirred at 0 °C, while barium carbonate (1.22g, 6.15mmol) was added, followed by the dropwise addition of bromine (727mg, 0.23mL, 4.55mmol). The yellow solution was stirred at 0 °C for 2 h and then for a further 2 h at room temperature. It was then filtered through celite and compressed air was bubbled through until the solution had been decolourised. The water was then removed *in vacuo* to afford a white solid. This white solid was pre-dried with acetone (2x50mL), before being suspended in acetone (100mL) and stirred at room temperature. 10-Camphorsulfonyl acid (192mg, 0.83mmol) was added and the mixture was stirred overnight. Tlc analysis indicated no change therefore another 0.2 equivalents of 10-Camphorsulfonyl acid (192mg, 0.83mmol) were added and the mixture was stirred at 50 °C for 4 h. The solution was filtered and the solvent was removed *in vacuo*. The crude residue was purified by column chromatography using heptane / ethyl acetate (2:1, v/v) as the eluent to afford (56) as a white solid (680mg, 68%). R_f 0.34 heptane /

Chemistry Towards P2 Hybrid Aminoacids

The general chemistry depicted in scheme 6 will shortly be published in full in the academic literature, by its inventors CS Dexter and RFW Jackson at the University of Newcastle, England.

(a) General Procedure for the zinc coupling reactions

(b) Zinc activation

Zinc dust (150mg, 2.3mmol, 3.0eq, Aldrich) was weighed into a 25mL round bottom flask with a side arm and fitted with a three way tap. The zinc powder was heated with a heat gun under vacuum and the flask was flushed with nitrogen and evacuated and flushed a further three times. With the flask filled with nitrogen, dry DMF (1mL) was added. Trimethylsilylchloride (30 μ l, 0.23mmol, 0.3eq) was added and the zinc slurry was vigorously stirred for a further 30mins.

(c) Zinc insertion; N-(*tert*-Butoxycarbonyl)-3-iodozinc-L-alanine methyl ester (61)

- 65 -

N-(*tert*-Butoxycarbonyl)-3-iodo-L-alanine methyl ester (247mg, 0.75mmol, 1.0eq) dissolved in dry DMF (0.5mL) was added dropwise, *via* cannula, to the activated zinc slurry at 0°C prepared as described above. The reaction mixture was then allowed to warm up to room temperature and stirred for 1 hr to give the organozinc reagent.

(d) CuBr.SMe₂ preparation

Whilst the zinc insertion reaction was in progress, CuBr.SMe₂ (20mg, 0.1mmol, 0.13eq) was weighed into a 25ml round bottom flask fitted with a three way tap and dried "gently" with a heat gun under vacuum until CuBr.SMe₂ changed appearance from a brown powder to give a light green powder. Dry DMF (0.5mL) was then added followed by addition of the electrophile (either 1-bromo-2-methylbut-2-ene, toluene-4-sulfonic acid-(E)-2-methyl-but-2-enyl ester or 1-bromo-2,3-dimethylbut-2-ene) (1.0mmol, 1.3eq). The reaction mixture was then cooled to -15°C.

(e) Coupling Reaction

Stirring of the organozinc reagent solution was stopped to allow the zinc powder to settle and the supernatant was carefully removed *via* cannula (care taken to avoid transferring too much zinc powder) and added dropwise to the solution of electrophile and copper catalyst. The cooling bath was removed and the solution was stirred at room temperature overnight. Ethyl acetate (20mL) was added and stirring was continued for a further 15mins. The reaction mixture was transferred to a separating funnel and a further aliquot of EtOAc (30mL) was added. The organic phase was washed successively with 1M Na₂S₂O₃ (20mL), water (2 x 20mL), brine (40mL), dried over sodium sulphate and filtered. The solvent was removed *in vacuo* and the crude product purified by flash chromatography on silica gel as described.

(f) Hydrogenation of alkene

The alkene (1.0mmol) was dissolved in ethanol (10mL), 10% palladium on carbon (80mg) added and hydrogen introduced. Once the reaction had been deemed to have reached completion, the hydrogen was removed, the reaction filtered through Celite and the catalyst washed with ethanol (30mL). The combined organic filtrate was concentrated *in vacuo* and the alkane used directly in the subsequent reaction.

(g) Saponification of methyl ester

The methyl ester (1.0mmol) was dissolved in THF (6mL) and whilst stirring, a solution of LiOH (1.2mmol, 1.2eq) in water (6mL) was added dropwise. Once the reaction was deemed to have reached completion, the THF was removed *in vacuo* and diethyl ether (10mL) added to the residue. The reaction mixture was then acidified with 1.0M HCl until pH = 3. The organic phase was then removed and the aqueous layer extracted with diethyl ether (2 x 10mL). The combined organic extracts were dried over magnesium sulphate, filtered and the solvent removed *in vacuo* to give the carboxylic acid used directly in the subsequent reaction.

(h) Removal of N-Boc protecting group

The N-Boc protected material (1.0mmol) was dissolved in DCM (2mL) and cooled to 0°C. Trifluoroacetic acid (2mL) was added dropwise and when the reaction was deemed to have reached completion, the solvents were removed *in vacuo* to yield the amine used directly in the subsequent reaction. Alternatively, the N-Boc protected material (1.0mmol) was cooled to 0°C and 4M HCl in dioxane (5mL) added dropwise and when the reaction was deemed to have reached completion, the solvents were removed *in vacuo* to yield the amine used directly in the subsequent reaction.

(i) Fmoc protection of amine

The amine (1.0mmol) in 1,4-dioxane (2mL) was cooled to 0°C and 10% sodium carbonate (2.2mmol, 2.2eq, 2mL) added. The biphasic reaction mixture was stirred vigorously and Fmoc-Cl (1.1mmol, 1.1eq) added. Once the reaction was deemed to have reached completion, diethyl ether (10mL) added and the reaction mixture acidified to pH = 3 with 1M HCl. The organic phase was removed and the aqueous layer extracted with diethyl ether (2 x 10mL). The combined organic extracts were dried over sodium sulphate, filtered, the solvent removed *in vacuo* and the residue purified by flash chromatography over silica gel.

General Solid Phase procedures

Molecules were assembled using the furanone building blocks and novel protected aminoacids described earlier, by solid phase procedures on Chiron multipins following the protocols detailed below.

Preparation of Crown Assembly

The compounds were synthesised in parallel fashion using the appropriately loaded Fmoc-Building block-linker-DA/MDA derivatised macrocrowns (see above) loaded at approximately 3.5 – 9.1 μ moles per crown. Prior to synthesis each crown was connected to its respective stem and slotted into the 8 x 12 stem holder. Coupling of the amino acids employed standard Fmoc amino acid chemistry as described in 'Solid Phase Peptide Synthesis', E. Atherton and R.C. Sheppard, IRL Press Ltd, Oxford, UK, 1989.

Removal of N α -Fmoc Protection

A 250 mL solvent resistant bath is charged with 200 mL of a 20% piperidine/DMF solution. The multipin assembly is added and deprotection allowed to proceed for 30 minutes. The assembly is then removed and excess solvent removed by brief shaking. The assembly is then washed consecutively with (200 mL each), DMF (5 minutes) and MeOH (5 minutes, 2 minutes, 2 minutes) and left to air dry for 15 minutes.

Quantitative UV Measurement of Fmoc Chromophore Release

A 1cm path length UV cell is charged with 1.2 mL of a 20% piperidine/DMF solution and used to zero the absorbance of the UV spectrometer at a wavelength of 290nm. A UV standard is then prepared consisting of 5.0 mg Fmoc-Asp(OBut)-Pepsyn KA (0.08 mmol/g) in 3.2 mL of a 20% piperidine/DMF solution. This standard gives $Abs_{290} = 0.55-0.65$ (at room temperature). An aliquot of the multipin deprotection solution is then diluted as appropriate to give a theoretical $Abs_{290} = 0.6$, and this value compared with the actual experimentally measured absorbance showing the efficiency of previous coupling reaction.

Standard Coupling Of Amino Acid Residues

Coupling reactions are performed by charging the appropriate wells of a polypropylene 96 well plate with the pattern of activated solutions required during a particular round of coupling. Macrocrown standard couplings were performed in DMF (500 μ l).

Coupling of an Amino-acid Residue To Appropriate Well

Whilst the multipin assembly is drying, the appropriate N_α -Fmoc amino acid pfp esters (10 equivalents calculated from the loading of each crown) and HOBt (10 equivalents) required for the particular round of coupling are accurately weighed into suitable containers. Alternatively, the appropriate N_α -Fmoc amino acids (10 equivalents calculated from the loading of each crown), desired coupling agent e.g. HBTU (9.9 equivalents calculated from the loading of each crown) and activation e.g. HOBt (9.9 equivalents calculated from the loading of each crown), NMM (19.9 equivalents calculated from the loading of each crown) are accurately weighed into suitable containers.

The protected and activated Fmoc amino acid derivatives are then dissolved in DMF (500 μ l for each macrocrown e.g. for 20 macrocrowns, 20 x 10 eq. x 7 μ moles of derivative would be dissolved in 10 mL DMF). The appropriate derivatives are then dispensed to the appropriate wells ready for commencement of the 'coupling cycle'. As a standard, coupling reactions are allowed to proceed for 6 hours. The coupled assembly was then washed as detailed below.

Washing Following Coupling

If a 20% piperidine/DMF deprotection is to immediately follow the coupling cycle, then the multipin assembly is briefly shaken to remove excess solvent washed consecutively with (200 mL each), MeOH (5 minutes) and DMF (5 minutes) and deprotected. If the multipin assembly is to be stored or reacted further, then a full washing cycle consisting brief shaking then consecutive washes with (200 mL each), DMF (5 minutes) and MeOH (5 minutes, 2 minutes, 2 minutes) is performed.

Addition of Capping Group

Whilst the multipin assembly is drying, the appropriate acid capping group (10 equivalents calculated from the loading of each crown), desired coupling agent e.g. HBTU (9.9 equivalents calculated from the loading of each crown) and activation e.g. HOBt (9.9 equivalents calculated from the loading of each crown), NMM (19.9 equivalents calculated from the loading of each crown) are accurately weighed into suitable containers. The acid derivatives / coupling agents are then dissolved in DMF (500 μ l for each macrocrown e.g. for 20 macrocrowns, 20 x 10 eq. of derivative would be dissolved in 10 mL DMF) and left to activate for 5 minutes. The appropriate derivatives are then dispensed to the appropriate wells ready for commencement of the 'capping cycle'. As a standard, capping reactions are allowed to proceed for 18 hours overnight. The capped assembly was then washed as detailed above.

Acidolytic Mediated Cleavage of Molecule-Pin Assembly

Acid mediated cleavage protocols are strictly performed in a fume hood. A polystyrene 96 well plate (1 mL/well) is labelled and weighed to the nearest mg. Appropriate wells are then charged with a trifluoroacetic acid/water (95:5, v/v, 600 μ l) cleavage solution, in a pattern corresponding to that of the multipin assembly to be cleaved.

The multipin assembly is added, the entire construct covered in tin foil and left for 2 hours. The multipin assembly is then added to another polystyrene 96 well plate (1 mL/well) containing trifluoroacetic acid/water (95:5, v/v, 600 μ l) (as above) for 5 minutes.

Work up of Cleaved Molecules

The primary polystyrene cleavage plate (2 hour cleavage) and the secondary polystyrene plate (5 minute wash) are then placed in the GeneVac evaporator and the solvents removed (minimum drying rate) for 90 minutes. The contents of the secondary polystyrene plate are transferred to their corresponding wells on the primary plate using an acetonitrile/water (50: 50 v/v/v) solution (3 x 150 μ l) and the spent secondary plate discarded. Aliquots (5-20 μ L) are taken for analysis. The plate was

covered in tin foil, pin-pricked over wells containing compounds, placed into the freezer for 1hr, then lyophilised.

Analysis and Purification of Molecules

The (5-20 μ L) aliquots are analysed by analytical HPLC and electrospray-MS. In virtually all cases, crude purities are >90% by HPLC with the desired m/z. Sample were purified by semi-preparative reverse phase HPLC, using Vydac C₄. Appropriate fractions are combined and lyophilised in tared 10mL glass vials, then re-weighed. Molecules were prepared on a 15-90 μ mole scale, yielding 2.0-26.0mg of purified products. The purity of each product was confirmed by analytical HPLC at >95% (215nm UV detection) and gave the appropriate [MH]⁺ by electrospray mass spectrometry analysis.

Loading of Macrocrowns With Constructs

General method for the loading of multipins with Dihydro-3(2H)-Furanone – Linker Constructs (29-34)

Amino functionalised DA/MDA macrocrowns (ex Chiron Mimotopes, Australia, 9.1 μ mole loading) or amino functionalised HEMA gears (ex Chiron Mimotopes, Australia, 1.3 μ mole loading) were used for all loadings and subsequent solid phase syntheses.

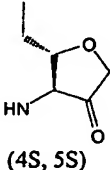

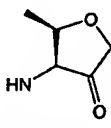

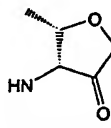

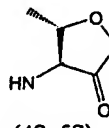

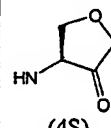

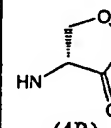

Dihydro-3(2H)-Furanone – Linker Construct (29-34) (3eq compared to total surface functionalisation of crowns / gears) was carboxyl activated with 2-(1H-benzotriazole-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (3eq), 1-hydroxybenzotriazole (3eq) and N-methylmorpholine (6eq) in dimethylformamide (5mL) for 5mins. This mixture was added to the crowns / gears, additional DMF added to cover the reaction surface and the mixture left overnight.

Standard washing and Fmoc deprotection readings (see procedures above) indicated virtually quantitative loading.

Exemplar molecules prepared by the methods detailed above are shown in Tables 1 and 2, together with a K_i (μM) measurement of inhibition verses mammalian, murine and rat cathepsins S and mammalian L and K.

The moieties shown in the following Tables 1 and 2 use the terms "CAP", "P1" and "P2" which can be cross referenced to the generic formula (II) as follows:

R1=CAP; R2=H; R3=the side chain of the aminoacid indicated as P2; R4=H, R5=the 5-substituent of the depicted furanone where the two right-most columns are comparative examples; and R6=H.

K, determinations for cathepsins S, L, and K**Cathepsin S (Mammalian, murine and rat)****General**

Assays were performed in 100 mM sodium phosphate, 100 mM NaCl, pH 6.5 (buffer) in white 384 well plates (Corning Costar). Eight inhibitors were assayed per plate.

Inhibitor dilutions

Inhibitor dilutions were performed on a 96 well V-bottomed polypropylene plate (Corning Costar). 100 µl of buffer was placed in wells 2-5 and 7-12 of rows A, B, C and D. Sufficient of each inhibitor at 10 mM in DMSO was placed into wells A1-D1 and A6-D6 to give the desired final concentration when the volume in the well was made up to 200 µl with buffer. Column 1 was made up to 200 µl with buffer, mixed by aspirating and dispensing 100 µl in the well, and 100 µl transferred to column 2. The pipette tips were changed and the mixing and transferral repeated to column 5. This process was repeated for columns 6-10.

Substrate dilutions

Substrate dilutions were performed on a 96 deep well polypropylene plate (Beckman Coulter). 280 µl of buffer was placed in wells B-H of columns 1 and 2. 70 µl of 10 mM boc-Val-Leu-Lys-AMC was placed in A1 and A2. 2 × 250 µl of buffer was added to wells A1 and A2, mixed by aspirating and dispensing 280 µl in the well, and 280 µl transferred to row B. The pipette tips were changed and the process repeated down the plate to row H.

Assay

Column 1 of the substrate dilution plate was distributed at 10 µl per well into alternate rows beginning at row A. Column 2 was distributed to alternate rows beginning at row B. Row A of the inhibitor dilution plate was distributed at 10 µl per well to alternate rows and columns starting at A1. Row B was distributed to alternate rows and columns starting at A2. Row C was distributed to alternate rows and columns starting at B1 and row D was distributed to alternate rows and columns starting at B2. The

- 88 -

assay was started by the addition of 30 μ l per well of 20 nM cathepsin S in buffer containing 10 mM 2-mercaptoethanol.

Data were saved as text files and imported into Excel. The initial rates were determined by linear regression and then fitted to the competitive inhibition equation using SigmaPlot.

Cathepsins L and K

Assays were performed essentially as above. For cathepsin L, the buffer used was 100 mM sodium acetate, 1 mM EDTA, pH 5.5 and the substrate was *D*-Val-Leu-Lys-AMC with a highest concentration of 100 μ M. For cathepsin K, the buffer used was 100 mM MES/Tris, 1 mM EDTA, pH 7.0 and the substrate was *D*-Ala-Leu-Lys-AMC with a highest concentration of 250 μ M.

(54) Title: FURANONE DERIVATIVES AS INHIBITORS OF CATHEPSIN S

(II)

(57) Abstract: Cathepsin S is a highly active cysteine protease belonging to the papain superfamily. It is found mainly in lymph nodes, spleen, and macrophages and this limited occurrence suggests the potential involvement of this enzyme in the pathogenesis of degenerative disease. The invention relates to novel protease inhibitors, particularly inhibitors of the cysteine proteases of the papain superfamily and more particularly to Cathepsin S. The inhibitors are Furanone derivatives of Formula (II) which have a characteristic non-hydrogen

substituent R₅. They are selective over other members of the family and in particular show selectivity over other members of the Cathepsin family such as L and K.
